Burden Hour Statement: This form is estimated to take 0.2 hours to complete. Time will vary depending upon the needs of the individual case. Any comments on the amount of time you are required to complete this form should be sent to the Chief Information Officer, Patent and Trademark Office, Washington, DC 20231. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Box Provisional Application, Assistant Commissioner for Patents, Washington, DC 20231.

STATEMENT CLAIMING SMALL ENTITY STATUS
(37 CFR 1.9(i) & 1.27(b)) - INDEPENDENT INVENTOR

Docket Number (Optional)

Applicant, Patentee, or Identifier: Gil Israeli, et al

Application or Patent No.:

Filed or Issued:

Title: Method and System for providing cellular communication services

As a below named inventor, I hereby state that I qualify as an independent inventor as defined in 37 CFR 1.9(c) for purposes of paying reduced fees to the Patent and Trademark Office described in:

☒ the specification filed herewith with title as listed above.

☐ the application identified above.

☐ the patent identified above.

I have not assigned, granted, conveyed, or licensed, and am under no obligation under contract or law to assign, grant, convey, or license, any rights in the invention to any person who would not qualify as an independent inventor under 37 CFR 1.9(c) if that person had made the invention, or to any concern which would not qualify as a small business concern under 37 CFR 1.9(d) or a nonprofit organization under 37 CFR 1.9(e).

Each person, concern, or organization to which I have assigned, granted, conveyed, or licensed or am under an obligation under contract or law to assign, grant, convey, or license any rights in the invention is listed below:

☒ No such person, concern, or organization exists.

☐ Each such person, concern, or organization is listed below.

Separate statements are required from each named person, concern, or organization having rights to the invention stating their status as small entities. (37 CFR 1.27)

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small entity is no longer appropriate. (37 CFR 1.28(b)).

Method and system for providing cellular communication services

FIELD OF THE INVENTION

The present invention relates generally to mobile telephone systems. More particularly, the present invention relates to a method of providing cellular communication services based on user location. The location of a mobile telephone within the geographic serving area of a mobile telephone systems is determined, and the system enables various services based on a defined geographic service scheme.

BACKGROUND OF THE INVENTION

Mobile telephone systems, also referred to as cellular telephone systems, have become increasingly popular. These systems are generally made up of cell sites, each of which serves a coverage area, or cell. The cell site is the location within a cell which contains the required hardware (e.g. antenna(s) and radio base station) to communicate with the mobile telephones. A mobile telephone operating within a particular cell in the system communicates with the mobile telephone system through the cell site covering that cell. The various cell sites are connected to a mobile switching center which connects the mobile telephone system to the land-line telephone network.

The widespread use of cellular systems and the low cost thereof have many advantages, such as high availability and freedom from cables. However, various problems arise from the use of wireless mobile telephones.

One of the problems with using mobile telephones stems from the electromagnetic radiation emitted from such devices, which might affect susceptible equipment. Various health authorities prohibit the use of wireless communications devices in hospitals.

Another problem associated with the use of cellular telephones arises when subscribers receive calls when attending activities requiring silence. Most cinemas and concert halls request their guests to shut-down all pagers and cellphones before the beginning of the show.

It is well known in the prior art that preventing use of cellular mobile phones may be implemented by transmitting a simple jamming signal on the control channel frequency transmitted by the cellular system, thereby disabling the mobile unit from communicating with the cellular system.

The jamming method for enforcement of cellphone usage policy has several drawbacks. First, in order to jam the cellular control (or paging) channel(s) one has to transmit a blocking signal using the same frequency band used by the cellular operators. When transmitting the jamming signal, one has to take precautions not to interfere with cellular communications outside the controlled area. It is well known to a man skilled in the art that precise control of electromagnetic radiation is a complex and expensive task.

Second, by jamming all communications between the cellular system and the mobile unit, the subscribers are totally disconnected from the cellular network and cannot use

50082618, 042298

In accordance with yet another aspect of the invention, the cellular system receives the location of the subscriber without any special action on the part of the mobile telephone or the mobile telephone user.

In accordance with another aspect of the invention, a clone base station front-end positioned in the regulated area communicates with mobile cellphones in the area, thereby controlling cellphone's availability and operation mode.

These and other advantages of the invention will be apparent to those of ordinary skill in the art by reference to the following detailed description and the accompanying drawings.

862240-8T928009

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be better understood and its numerous objects and advantages will become more apparent to those skilled in the art by reference to the following drawings, in conjunction with the accompanying specification, in which:

FIG. 1 is an illustrative diagram describing a typical cellular system composed of 7 cell sites, each having a base station incorporating a transceiver.

FIG. 2 is a functional diagram illustrating the components of a cellular system included in one embodiment of the present invention.

FIG. 3 shows a cellular telephone system regulated area location system in accordance with one embodiment of the present invention.

FIG. 4 is a block diagram of one preferred embodiment of the location system digital signal processing.

FIG. 5 is a flow diagram illustrating the steps performed by the present invention when a mobile user originates a call.

DETAILED DESCRIPTION

FIG. 1 illustrates a basic cellular system having 7 hexagonal cells numbered 1-7. Cell 7 is shown in the center, surrounded by adjacent cells 1-6. The serving area of a mobile telephone system would typically contain more than 7 cells, however, for ease of reference, only 7 cells are shown in FIG. 1. Each cell 1-7 contains a base station including a transmitter, receiver and base station controller as are well known in the art. The base station transmitter/receiver is connected to an antenna tower 11-17 which is used to transmit signals to, and receive signals from, mobile telephones, within the mobile telephone system serving area. In FIG. 1 the base stations antenna towers 11-17 are selected to be located at the center of each of the cells 1-7, respectively and are equipped with Omni-directional antennas. However, in other configurations of a cellular radio system, the base station towers 11-17 may be located near the periphery, or otherwise away from the center of the cells 1-7 and may illuminate the cells 1-7 with radio signals either Omni-directionally or directionally. Therefore, the representation of the cellular radio system of FIG. 1 is for purposes of illustration only and is not intended as a limitation on the possible implementations of a mobile radio communications system within which a regulated area is defined for the purpose of locating subscribers and providing location oriented services. A regulated area 10 is located within cell 7, and a plurality of mobile units are used across the entire serving area within cells 1-7. Again, only one regulated area is shown in FIG. 1, but it should be understood that the actual number of regulated areas can be larger, in practice.

Each cell 1-7 has assigned to it a plurality of voice or speech channels for transmitting and receiving voice signals, and at least one access or control channel for transmitting control data signals, such as a forward control channel, and receiving control data signals from the mobile units, such as a reverse control channel. Referring to FIGS. 1 and 2, consider mobile telephone unit 22 which is operating in cell 7. The mobile unit

862249-87928009

22 is communicating over the air interface with the mobile telephone system via base station antenna 24. Voice signals are communicated between the mobile unit 22 and the antenna 24 via one of the cell's voice channels, and control data signals are communicated between mobile unit 22 and the antenna 24 via the cell's control channel. The control channel is used to control or supervise the operation of the mobile unit by means of information transmitted and received from these units, referred to as messages. Control and administration messages within a cellular radio system are sent in accordance with industry established air interface standards, such as AMPS and EIA/TIA 553, the standards for analog cellular operations, and/or D-AMPS, IS-54 and IS-136, the standards for digital cellular operations, all of which are hereby incorporated by reference herein. Similar standards such as IS-95 for Code Division Multiple Access (CDMA) and Global System for Mobiles (GSM) govern other geographic areas throughout the world, and are well known to those skilled in the art.

A mobile telephone system in accordance with one embodiment of the present invention is shown in FIG. 2. The mobile unit 22 is a digital mobile telephone which operates according to the North American Time Division Multiple Access (TDMA) system IS-55 standard, and the air interface is described by the IS-54 and IS-136 standards. See, EIA/TIA Interim Standard IS-54-B "Cellular System Dual-Mode Mobile Station--Basestation Compatibility Standard", April, 1992; EIA/TIA Interim Standard IS-136 "Cellular System Dual-Mode Mobile Station--Basestation: Digital Control Channel Compatibility Standard", April, 1995. Each cell 1-7 within the mobile telephone system serving area contains a cellular base station antenna tower 24 which is connected to the mobile telephone switching office (MTSO) 25.

In such a situation, cell 7 is the serving cell since the voice data is being communicated through that cell. In addition to the communication with the serving cell, the mobile unit 22 also monitors the control channels of nearby cells.

The information exchanged between base stations and mobile units via messages, may include incoming call signals, outgoing call signals, paging signals, paging response signals, location registration signals, voice channel assignments, maintenance instructions and handoff instructions as the mobile units travel out of the radio coverage of one cell and into the radio coverage of other cells, as well as other additional items of information such as calling party numbers, time information and the like. The control or voice channels may operate in either analog or digital mode or a combination thereof based upon industry standards.

The regulated area 21 is located within the coverage area of the cell site. The mobile unit 22 shown within the regulated area communicates with the cellular base station 24 via an air interface. A front-end module 23 is installed within or near the regulated area 21. The front-end module monitors the radio messages transmitted by the mobile unit 22 and determines if the unit is located within the regulated area. The front-end module 23 communicates with the cellular base station 24 via the reverse control channel and notifies the MTSO 25 of all mobile units currently located within the regulated area. The MTSO 25 includes a service management unit (SMU) 26. The SMU includes software that runs and updates a database of all cellular subscribers current location and profile. And a data resulting in a digital map of regulated areas. The data received from the front end is compared to data from other sources, in order to improve the

60032618-042298

accuracy of the location coordinates, and determine whether the user is actually inside the regulated area. The SMU determines what services are currently available to each user. Whenever a mobile unit located within a regulated area requires service from the cellular system (e.g. initiates or receives a call), the MTSO checks the user database if such service conforms with the defined usage policy.

Usage policy in regulated areas may differ in accordance with the Mobile Identification Number (MIN) or the Electronic Serial Number (ESN) resulting in different services available to different mobile unit, as a function of the user location and profile definition.

Since various cellular operators use different methods for locating their subscribers, at various levels of accuracy, a disclosure includes an optional method and system for locating subscribers within defined areas. The describes location method may be used in addition to other location methods and systems, and may not be required where the cellular system is able to derive accurate enough positioning data.

FIG 3. illustrates one embodiment of the present invention wherein a defined regulated area 31 are one or more mobile units. Only one mobile unit 32 is shown in FIG. 3, but it should be understood that the actual number of mobile units may be larger. The presence or absence of mobile units in any particular regulated area should be understood to depend, in practice on the individual desires of subscribers utilizing the mobile units. A plurality of mobile units, such as mobile unit 32 shown in FIG. 3 are used outside the regulated area 31. A front end unit 34 is located within or near the regulated area 31. The front end unit 34 incorporates an array of receiving antennas 35 comprising a plurality of antennas separated from each other so as to enable accurate intersection of the signals transmitted from the mobile units nearby the regulated area 31. In the illustrative example of FIG. 3, three receiving antennas 36-38 are utilized to determine the location of a mobile unit 32. While three receiving antennas 36-38 are utilized in the illustrative example of FIG. 3, it should be understood that a different number may be utilized in practice. The present invention monitors all messages transmitted by the mobile units located in the vicinity of regulated area 31 vis-a-vis the antenna array 35 connected to the front end unit 34. By measuring signal strength, propagation delay, or both from each of the receiving antennas 36-38, the distance of the mobile unit 32 from each antenna is calculated. Arcs of possible locations of the mobile unit are then derived from the calculated distances. Well known geographical intersection techniques such as triangulation, arculation, probability density functions, and the like are then used to calculate the location of the mobile unit. The front end unit 34 converts the measured signal strength, propagation delay, or both from each of the antennas 36-38 into digital format and transmits the measured values to a nearby base station 39. In the preferred embodiment, all measurements from various base stations are relayed to the MTSO, wherein a processor unit 30 calculates the location of all mobile units in the vicinity of regulated areas wherein a front end unit is installed. It should be understood that the location of the processor unit may be either within the front end unit 34 or within the base station 39 as well as the MTSO 30. Preferred embodiments of the present invention make significant use of digital signal processing techniques. Such techniques entail the use of appropriate forms of sampling and conversion hardware to convert analog radio frequency signals into sampled digital data forms. These techniques are widely known in the art, and are capable of performing many functions traditionally implemented using analog components. The

50082618-042298

advantage of using digital signal processing includes better control of noise during conversion, sampling, and filtering; and exact replication of these functions from each receiving antenna. Since the front end unit serves as a conversion facility to digital signals, it becomes technically immaterial where the actual processing is performed. Thus, the digital measurements can be processed either within the front end unit or at any other location such as a base station or the MTSO. Moreover, one skilled in the art will recognize that in a commercial implementation of the present invention, the actual location of the processor is a cost tradeoff involving the cost of digital signal processing subsystems and the cost of transferring the raw digital measurements from the front end units to the MTSO.

FIG. 4 illustrates a typical location technique disclosed in U.S. Patent No. 5,608,410 to Stilp et al entitled "SYSTEM FOR LOCATING A SOURCE OF BURSTY TRANSMISSIONS CROSS REFERENCE TO RELATED APPLICATIONS", which is incorporated by reference herein. It should be noted that the present invention is not limited to the Stilp method and any other sufficiently accurate location method can be utilized. Referring to FIG. 4, the front end unit is made up of an elevated ground-based antenna array comprising three antennas receives transmissions from mobile units over the reverse control/access channel, typically of the nearest cell site. Signals received by each antenna are fed into a sampler 41, which converts the sampled signals into frames of digital data at a prescribed sampling frequency. Each frame of data comprises a prescribed number of data bits and time stamp bits that represent the time at which the responsive signal was received. Baseband converters 42 receive the sampled signals and provide a baseband signal derived therefrom. A multi-antenna processor 43 combines and distinguishes the signals received from the individual antennas in the antenna array, and then provides a single representation of a signal for further processing. A transmission demodulator 44 determines the demodulated data content of the responsive signal, where the demodulated data content includes information identifying the mobile unit, possibly its electronic serial number (ESN) and/or mobile identification number (MIN). A database subsystem 45 determines how and whether a responsive signal should be stored for further processing, or whether it should be discarded. A signal processor 46 extracts selected signal characteristics from the frames of digital data, such as timing, power, frequency and phase. A data reduction and forwarding subsystem 47 selects and compresses the data frames before transmission over communications facilities to the central site (MTSO). A timing module 48 determines a synchronization signal common to all the antenna site components. The system is self-calibrated by a calibration module 49 which determines and corrects changes in delay, frequency and phase of various site components.

FIG. 5 is a flow diagram illustrating the steps performed by the SMU when a mobile phone subscriber originates a call when located in the regulated area. The system begins in FIG. 5 at step 51 where a user originates a call to a land subscriber. As the user's request for service is received, the system moves to step 52 and checks the user's position, and optionally updates it with new data. At step 53 the SMU determines the accuracy of the user's location. If the system determines that the user's location is not sufficiently accurate then the system moves to step 57 and provides the default level of service or a level of service defined for inaccurate positioning in the vicinity of the regulated area. If it is determined that the user's location is accurate the system proceeds to step 54 and determines the defined usage policy for the user's

60032618-042298

location. If at step 54 it is determined that the user's current location is not defined as having a specific usage policy then the system moves to step 57 and provides the default level of service. If, at step 54 it is determined that the user's current location has a defined usage policy then the system proceeds to step 55 where it is determined if the said user (or user group) has a specific permission which overrides the general definitions of the level of service available in the regulated area. If at step 55 it is determined that the user has a specific permission, then the system moves to step 58 and provides the level of service designated to said user. If, however, at step 55 it is determined that said user does not have a specific permission, then the system proceeds to step 56 where the service rendered to the user is determined in accordance with the usage policy defined to its current location. The steps illustrated in FIG. 5 are followed both when the service is initiated by the mobile user or when the user is totally passive and the call or message is initiated by another subscriber, whether mobile or land based.

Table 1 describes a basic usage policy database for a cellular system in accordance with one embodiment of the present invention. Line 1 sets the basic rule - all subscribers are allowed access to all services at all time. Line 2 denies all cellular services from all subscribers located within the hospital at all time. Lines 3 and 4 limit all subscribers located at the concert hall (except 245677) to SMS services only during the concert time (22:00-24:00). Line 9 provides additional services to User 518603 when located in the company factory area, including wider bandwidth for network connection and video conferencing, better quality of service, reduced price, conference call service etc.

Table 1

No.	Subscriber MIN	Location	Time	Services Allowed	Services Denied
1.	ALL	ALL	ALL	ALL	
2.	ALL	Hospital	ALL		ALL
3.	ALL	Concert hall	22:00-24:00	SMS	ALL
4.	245677	Concert hall	ALL	ALL	
5.	ALL	Cinema	22:00-24:00	SMS	ALL
6.	230882	Cinema	ALL	ALL	
7.	ALL	Public library	ALL		ALL
8.	586362	Public library	ALL	ALL	
9.	586362	Company factory	ALL	ALL+64kbps Bandwidth	

Similarly, the availability and price of additional services may be determined respective to MIN and user profile definitions versus, user current location and regulated areas database.

862240-8T928009

In one embodiment of the present invention, areas such as corporate office buildings are divided into sections. The SMU manages communications services and resources according to user location.

The SMU receives user location data as described, and sends commands to the MTSO, and other subsystems of the cellular network, to determine the services to be provided to users in the designated location. Therefore, when a mobile cellular subscriber enters designated areas, incoming calls may not be directed to the user cellphone at all, or may be redirected as an incoming call to the nearest available wireline telephone extension. SMU may also manage and control the availability of resources managed by the corporate premises therein. In order to control availability of resources managed by the corporate, the SMU typically communicates via the cellular telephone network with a resource management unit at the corporate office building. For example, the SMU detects the presence of a specific user in the office and (1) signals to the computer via the wireless network to grant/deny access to computer applications, networks and files and determines database permissions; (2) Similarly, by communicating with a control unit, by means of wireless modem, the SMU enables or disables specific auxiliary services and resources available in said designated area, such as managing availability of equipment, printers, lab equipment, communication and video conferencing utilities etc; (3) The SMU, via wireless network and control unit at the corporate end, equipped with wireless modem, may allow/deny physical access to specific rooms; (4) grant/deny access to classified information in physical cabinets; (5) determine employee presence at the office and perform time logging; (6) and broadcast general messages pertinent to users in specific locations, such as messages regarding fire alarm, security alarm etc.

The foregoing Detailed Description is to be understood as being in every respect illustrative and exemplary, but not restrictive, and the scope of the invention disclosed herein is not to be determined from the Detailed Description, but rather from the claims as interpreted according to the full breadth permitted by the patent laws. It should be understood that the Services Management Unit (SMU) software typically located at the MTSO, may be located in the regulated area and communicate with cellular network MTSO or base stations as required. It is to be understood that the embodiments shown and described herein are only illustrative of the principles of the present invention and that various modifications may be implemented by those skilled in the art without departing from the scope and spirit of the invention. For example, the detailed description described a method for calculating a location estimate by using three signal strengths. However, the principles of the present invention could be extended to perform such a calculation using more than three signal strengths or different means for calculating the estimated location of the mobile unit. Such an extension could be readily implemented by one of ordinary skill in the art given the above disclosure. The presence of the cellphone in the regulated area may also be established by detecting the cellphone using a positioning front end as a registry at the entrance, corridor, or gate to the regulated area. The SMU will then extract a database of the actual position of the cellphone users at any given time according to the gates they passed and the positioning front end they have communicated with upon entering and exiting regulated areas....

50082618-042208

In another embodiment selective, location orientated control of cellular services is achieved by positioning a phantom base station in the controlled location. The phantom base station simulates base station signaling in order to communicate with the mobile phones in the location. The mobiles in the controlled location receive the clone signaling from the nearby transmitter at a superior signal to noise ratio, and respond to the clone signaling rather than to the actual cellular system base station. The clone station simulates signaling respective to the required control and limitation of cellular services in the controlled area. The clone station is capable of performing cellphone registration, transmitting protocol signals that disable all mobiles from receiving incoming calls, and transmitting protocol signals that disable selected services only. A clone station receiver enables simulated communication with cellphones. The receiver enable the clone station to recognize cellphones with specific Mobile Identification Numbers (MINs), predefined in the clone station database, referring these selected users to use the actual base station operating in that area. The selected users will still receive regular cellular services, and will be capable of receiving incoming calls and other services.

In yet another embodiment, a messaging center is incorporated into the service management unit (SMU). When a mobile subscriber is located within a regulated area and the usage policy defined for said subscriber denies voice communications, the user is normally unavailable. Subscribers having voice mail messaging can route the incoming call to their personal mailbox. However, subscribers who do not have voice mail messaging remain unavailable. The present invention incorporates an autonomous messaging system, intended for cellular subscribers who do not have a personal mailbox. When a non-voice mail cellular subscriber located within a regulated area is called, the messaging system enables the caller to leave a message in a temporary mailbox. When the non-voice mail cellular subscriber departs the regulated area, the messaging system calls the non-voice mail cellular subscriber and notifies him that one or more messages are available for him. In cellular systems where a Calling Party Pays (CPP) billing scheme is implemented, the charges for the messaging service may be billed to the calling party, at his consent. Alternatively, the voice mail message may be handled by the non-voice mail cellular subscriber as a collect call, which has to be specifically accepted in order for billing to take place. It should be understood that the messaging system presented herein may provide services for voice, fax, data and video. The messaging system may be implemented within a wireline telephony system.
